Reflection on system requirements

The system meets all the minimal requirements as stated in the assignment details. However, there is definitely room for improvement in a lot of aspects, such as the structure in which products are displayed, etc. Also, since the assignment details were vaguely stating features the program should have, there was a lot of loose interpreting that was done. For instance, it wasn't stated what kind of interface the user should be greeted with, rather focused on the functionality it should have. Thus, I decided to implement a membership interface where the customer has to verify their membership in the market and then is sent directly to add items to their cart.

Challenges Faced and Solutions

Everything felt rather trivial in terms of the program, it was mainly designing what kind of system it should be whether it would display a login or jump straight into adding items into a cart. I ultimately decided on a sort of login system so it would be easy for an admin to access the system. The admin would then be given an admin menu where they can perform a number of actions as stated in the assignment details and things I found would make checking inventory, customer information, etc. easier.

In terms of the program, the thing that was a bit annoying to code was the functions to write back to the CSV files. I was having an issue for a short while where the CSV files would bug and not finish being written to, like a cut off. I found out it was due to not closing the **PrintWriter** after use.
